

Abstract of Disclosure

When the print object conversion method is realized as a printer driver, first, a print object print request is received from an application. Then, intermediate data are generated from the print object and an object classification table is generated from the print object in parallel with the execution of generating intermediate data. Next, the object classification table and operating environment of the computer are compared to a PDL decision table prepared beforehand, and a single PDL is selected from among a plurality of PDLs. In PDL data generation, PDL data described in the selected PDL are generated from the intermediate data. The generated PDL data are output to the printer.
